FTP & SNMP PRACTICAL ASSIGNMENT

FileZilla Server • FileZilla Client • File Transfer • SNMP • FTP vs HTTP

Student Name: _____ **Class:** _____
Date: _____ **Subject:** Networking

Note: Complete the practical steps on your own Windows computer or a lab machine you are authorized to use. Add your actual screenshots and results in the spaces provided. Do not expose an FTP server directly to the public internet.

1. Install FileZilla Server and create a shared folder

1. Download FileZilla Server from the official website: **https://filezilla-project.org/**.

2. Run the installer and follow the setup wizard. Keep the default settings unless your instructor asks you to change them. Finish installation and open the FileZilla Server administration interface.

3. Create a folder on your computer for FTP sharing, for example **C:\FTPShare**. Put a test image in this folder later, or use it as the server's shared folder.

4. In the FileZilla Server administration interface, create a user account (for example, a username of your choice) and set a strong password.

5. Open the shared folders / mount points section for that user. Add the folder you created and give the user the required permissions, such as read, write, and list, for this lab.

6. Check the server's listening settings and firewall permissions. For a local-only lab, connect using 127.0.0.1. If connecting from another computer on your private lab network, allow the required FTP ports only on that trusted network.

Screenshot: Attach a screenshot showing the FileZilla Server user and shared-folder configuration (hide the password).

My FTP shared folder path: _____

FTP username created: _____ **(Do not write the password here.)**

2. Connect with FileZilla Client and upload an image

1. Install and open FileZilla Client from the official FileZilla website.

2. In the connection fields, enter:

```
Host: 127.0.0.1        (if the server and client are on the same PC)
Username: your FTP username
Password: the password you created
Port: 21                (if using the default FTP control port)
```

3. Click Quickconnect. If the server and client are on different computers, use the server computer's private LAN IP address instead of 127.0.0.1.

4. In the left panel (Local site), find an image file on your computer. In the right panel (Remote site), open the shared FTP folder. Drag the image from left to right to upload it.

5. Check the transfer queue and confirm that the upload completed successfully.

Screenshot: Attach a FileZilla Client screenshot showing the uploaded image in the remote folder. Do not show your password.

3. Download the uploaded file and compare its size

1. Create a different destination folder on your computer, for example **C:\FTPDownload**.

2. In FileZilla Client, keep the remote shared folder open on the right panel. Open the new destination folder on the left panel.

3. Select the uploaded image on the right panel and download it to the new folder on the left (right-click → Download, or drag it from right to left).

4. In Windows File Explorer, right-click the original image and downloaded image, choose Properties, and compare their file sizes. The sizes should match if the transfer completed correctly.

Record your result:

File information	Original file	Downloaded file
File name	_____	_____
File size (bytes / KB / MB)	_____	_____

Result: Do the two file sizes match? Yes / No Notes: _____

Screenshot: Attach a screenshot of the downloaded file in the new folder and/or its Properties window.

4. Three real-world uses of SNMP in network management

SNMP (Simple Network Management Protocol) helps network administrators monitor and manage network devices. It can collect information such as device status, bandwidth usage, CPU load, memory use, errors, and uptime.

Scenario 1 – ISP network monitoring: An Internet Service Provider can use SNMP to monitor routers, switches, and link bandwidth. Admins can identify high traffic, interface errors, or a device that has stopped responding, helping them troubleshoot slow or unavailable internet services.

Scenario 2 – Campus or office Wi-Fi: A school, college, or office network team can monitor wireless access points and switches. SNMP data can help show whether an access point is online, how much traffic a network link carries, or whether a device is overloaded.

Scenario 3 – Data centre or large website infrastructure: A company hosting apps or websites can monitor switches, routers, firewalls, and servers that support its services. SNMP monitoring can help detect device failures, high interface utilization, and uptime problems before they affect users.

My examples / notes:
1. _____
2. _____
3. _____

5. Comparison between FTP and HTTP

The table below compares common characteristics. Port numbers shown are the standard defaults; secure variants use different ports.

Point	FTP	HTTP
Full form	File Transfer Protocol	Hypertext Transfer Protocol
Default port	TCP 21 for control; traditional data transfer uses a separate connection (commonly TCP 20 in active mode)	TCP 80
Security	Basic FTP is not encrypted. Use FTPS or SFTP when sensitive files are involved.	HTTP is not encrypted. HTTPS is the secure HTTP protocol. TLS, usually on
Data transfer method	Designed for uploading and downloading files between clients and servers.	Transfers web resources such as HTML pages, images, scripts, and A
Common use cases	File sharing, website file publishing, and moving files to/from a server.	Browsing websites, loading web apps, and communicating with web A
Authentication	Can use a username and password; anonymous access may also be configured.	May use cookies, tokens, passwords, or other application-level metho

Conclusion

In this practical, I learned how to set up an FTP server, create a user and shared folder, upload and download a file using FileZilla Client, understand real-world SNMP monitoring, and compare FTP with HTTP.
